How do we know that smoking

## causes lung cancer?

Seif Shaheen
Professor of Respiratory Epidemiology

## Centre for Primary Care and Public Health

Blizard Institute
Barts and The London School of
Medicine and Dentistry
s.shaheen@qmul.ac.uk

Objectives

- Cohort studies
- Prospective and historical
- Strengths and weaknesses
- Measuring risk
- Absolute risk, relative risk
- Attributable risk, population attributable fraction
- Causality
- Criteria for causal inference
- Using genetic epidemiology

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

## Conducting a cohort study: five steps

- Select cohort population
- Measure exposure
- Follow-up
- Measure disease outcome
- Estimate disease risk associated with exposure

## Selection of exposed and non-exposed groups

- Common exposures eg smoking, diet $\qquad$
- General population cohort
- Internal comparisons of exposure status $\qquad$
- Rare exposures
- Cohort defined by geography, environmental exposure/disaster
- Montserrat volcano
- Cohort defined by occupation eg asbestos workers
- Internal comparison (other workers in same industry)
- External comparison (workers in different industry)

## Measuring exposure to risk factors

$\qquad$

- Records
- Hospital eg birth weight
- Occupational eg dust exposure
- Environmental monitoring
- dust mite, $\mathrm{NO}_{2}$ levels in air $\qquad$
- Lifestyle questionnaire
- smoking, diet, occupation
- Clinical/biochemical/molecular measurement $\qquad$
- Body Mass Index, nutrient biomarker, genotype

## Follow-up

- A challenge!
- Chronic diseases have long latent period
- Optimising follow-up
- stable population eg Isle of Wight, Framingham
- motivated population eg health personnel
- regular contact and tracing
- important to minimise BIAS

## Measuring outcome

$\qquad$

- Records $\qquad$
- Mortality
- Death certificates
- morbidity
- Health care records
- Interview / examination
- questionnaire (standardised / validated)
- chronic bronchitis
- asthma
- clinical/biochemical $\qquad$
- lung function, blood pressure, blood sugar

## Categorising exposure for analysis

$\qquad$

- "Natural" categorical variable $\qquad$
- Smoker
- Yes/No
- Never/Ex/Current
- Categorical variable from continuous variable
- body mass index
- <20; 20-24.99; 25-29.99; $\geq 30$
- Quantiles $\qquad$
- More than two categories is more informative
- "Dose-response"

## Defining outcome for analysis

- Binary outcome: Yes/No
- Death; asthma
- Analyse risk
- Continuous outcomes eg lung function, bp
- Define "disease" (Yes/No) using cut-off
- Eg COPD: $\mathrm{FEV}_{1} /$ /FVC<70\%
- Analyse risk
- Keep continuous outcome
- Analyse difference in mean outcome between exposure groups

Comparing disease risk in exposed and non-exposed (1)

- Count number of new cases of disease in each exposure group
- Risk (incidence) of disease
= number of new cases during defined period total number at risk at start of period $\qquad$
- Relative risk (risk ratio) = risk in exposed risk in non-exposed

| Calculating the relative risk |  |  |  |
| :---: | :---: | :---: | :---: |
| Develop disease |  |  |  |
|  | Yes | No | Total |
| Exposed |  |  |  |
| Yes |  | b | a+b |
| No | c | d | c+d |
| Relative risk $=\frac{a /(a+b)}{c /(c+d)}$ |  |  |  |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

## Obesity and adult-onset asthma

- Nurses Health Study, USA
- 85, 911 participants aged 26-46 in 1991 $\qquad$
- Body Mass index measured at baseline
- Followed up for 4 years $\qquad$
- Outcome measure: incident asthma

Arch Intern Med 1999; 159: 2582-8

| Obesity and adult-onset asthma |  |  |  |
| :---: | :---: | :---: | :---: |
| Develop asthma |  |  |  |
|  | Yes | No | Total |
| Obese |  |  |  |
| Yes ( $\mathrm{BMI} \geq 30$ ) | 398 | 10,805 | 11,203 |
| No | 1,198 | 73,510 | 74,708 |
| $\text { Relative risk }=\frac{398 / 11,203}{1,198 / 74,708}=2.22(1.98-2.48)$ |  |  |  |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Obesity and adult-onset asthma $\qquad$

| BMI | Adjusted RR (95\% CI) |
| :--- | :---: |
| $<20$ | $0.9(0.7-1.1)$ |
| $20-22.4$ | 1.00 |
| $22.5-24.9$ | $1.1(1.0-1.3)$ |
| $25.0-27.4$ | $1.6(1.3-1.9)$ |
| $27.5-29.9$ | $1.7(1.4-2.0)$ |
| $\geq 30$ | $2.7(2.3-3.1)$ |

$\qquad$

$\qquad$
$\qquad$

Paracetamol and adult-onset asthma: Nurses Health Study

Frequency of use (days
per month) Adjusted RR(95\% CI)

| None | 1.0 |  |
| :--- | :--- | :--- |
| $1-4$ | 1.27 | $(0.96$ to 1.66$)$ |
| $5-14$ | 1.43 | $(0.99$ to 2.07$)$ |
| $15-21$ | 1.78 | $(1.04$ to 3.04$)$ |
| $22+$ | 1.53 | $(0.95$ to 2.46$)$ |

Leisure time physical activity and risk of death

- Copenhagen City Heart Study, Denmark
- 7,023 men and women aged 20-79
- Physical activity measured in 1976-8 and 1981-3
- 1424 men and 1301 women died during 17-year follow-up

## AJE 2003; 158: 639-44

Physical activity and mortality risk

| Level of activity at 2nd exam in those who had low activity at first exam | $\begin{gathered} \text { Men } \\ \mathrm{RR}^{*}(95 \% \mathrm{CI}) \end{gathered}$ | $\begin{gathered} \text { Women } \\ \text { RR* }^{*}(95 \% \mathrm{Cl}) \end{gathered}$ |
| :---: | :---: | :---: |
| Low | 1.00 | 1.00 |
| Moderate/high | 0.64 (0.50, 0.81) | 0.74 (0.58, 0.95) |
| *Adjusted relative risk |  |  |

Comparing disease risk in exposed and non-exposed (2)

- Rate
number of new cases during defined period $\qquad$ total "person time at risk" during period
- Relative rate (rate ratio) = rate in exposed rate in non-exposed

## Nut consumption and CHD

- Nurses Health Study, USA
- 1980-1994
-1,132, 229 person years of follow-up
- Dietary questionnaire at baseline
- nut consumption
- 1255 new cases of coronary heart disease

Hu et al, BMJ 1998; 317: 1341-45

| Nut consumption and CHD |  |  |  |
| :---: | :---: | :---: | :---: |
| Freq of eating nuts | Cases | Person years | RR* ${ }^{\text {( }}$ 5\% CI) |
| Never | 542 | 391,918 | 1.0 |
| <2x/week | 584 | 579,805 | 0.91 (0.81,1.03) |
| 2-4x/week | 85 | 102,175 | 0.78 (0.61,0.99) |
| $\geq 5 \mathrm{x} /$ week | 44 | 58,330 | 0.66 (0.47,0.93) |
| *adjusted Relative Rate |  |  | P trend 0.005 |

## Prospective cohort studies

## - Strengths

- study rare exposure
- study multiple effects of one exposure $\qquad$
- demonstrate temporality
- minimise bias in exposure measurement $\qquad$
- measure incidence
- Limitations $\qquad$
- inefficient for rare diseases
- costly and time-consuming
- potential bias from losses to follow-up

## Historical cohort studies

$\qquad$

- How do they differ from prospective cohort $\qquad$ studies?
- Outcome of interest has already occurred when $\qquad$ study begins, therefore efficient for diseases with long latent periods $\qquad$
- How do they differ from case control studies? $\qquad$
- Individuals selected according to documented exposure status (historical records) $\qquad$
$\qquad$

$\qquad$

Atopy according to measles history in $\qquad$ 14-21year-olds in Bissau ( $n=262$ )

|  | Atopy |  |
| :--- | :---: | :--- |
|  | $\%$ | OR* $^{*}(95 \% \mathrm{CI})$ |
| Measles |  |  |
| No (n=129) | 25.6 | 1.0 |
| Yes $(\mathrm{n}=133)$ | 12.8 | $0.36(0.17,0.78)$ |

* controlling for potential confounders

Why is it potentially misleading just to report the relative risk or odds ratio?

- The RR or OR only tells us about the aetiological, not public health, importance of an exposure $\qquad$
- The RR or OR alone may lead to "hype" by the media and unnecessary alarm for the public

How important are findings for Public Health? $\qquad$

- How many excess cases among exposed can be $\qquad$ attributed to exposure?
- Attributable risk $\qquad$
- What proportion of disease in the population can be $\qquad$ attributed to exposure?
- Population Attributable Fraction
- Gives an idea of scope for prevention if exposure removed (assuming causal relation)
$\qquad$
$\qquad$
$\qquad$

| Nurses' Health Study: Risk of primary PE by postmenopausal hormone use (1) |  |  |  |
| :---: | :---: | :---: | :---: |
|  | es | rson-years | $\mathrm{RR}^{*}(95 \% \mathrm{Cl})$ |
| HRT use |  |  |  |
| Never | 27 | 320,339 | 1.0 |
| Current | 22 | 155,669 | 2.1 (1.2 to 3.8) |
| * adjusted relative rate |  | (Grodstein et al. Lancet 1996) |  |

| Nurses' Health Study: Risk of primary PE by postmenopausal hormone use (2) |  |  |  |
| :---: | :---: | :---: | :---: |
|  | Cases | Person-years | Absolute rate |
| $\begin{aligned} & \text { HRT } \\ & \text { use } \end{aligned}$ |  |  |  |
|  |  |  |  |
| Never | 27 | 320,339 | $8 / 100,000 / \mathrm{yr}$ |
| Current | 22 | 155,669 | 14/100,000/yr |
| $\begin{aligned} \text { Attributable Risk }= & \text { risk in exposed }- \text { risk in non-exposed } \\ & =6 \text { cases } / 100,000 \text { women } / \text { year } \end{aligned}$ |  |  |  |

The importance of reporting absolute and attributable risks

- Puts research findings (RRs and ORs) into
$\qquad$ perspective
- For policy makers $\qquad$
- Do we need to do anything about this risk factor?
- "all policy decisions should be based on absolute measures of risk; relative risk is strictly for researchers only" (Geoffrey Rose, 1991)
- For the public
- Should we be worried about this risk factor?
- Enables fuller interpretation and better communication of risk

## Does asthma begin in utero?

- Early presentation
- Prenatal risk factors
- Maternal smoking in pregnancy
- Antibiotic use in pregnancy
- Infections in pregnancy
- Complications of pregnancy
- Mode of delivery
- Gestational age at birth
- Anthropometry at birth

Avon Longitudinal Study of Parents and Children (ALSPAC)

- Prospective study of 14,541 pregnancies $\qquad$
- 14,062 live births
- 13,988 survived to 1 year
- Eligible
- EDD 1.4.91-31.12.92
- resident in Bristol health districts $\qquad$
- Enrolled
- as early as possible in pregnancy $\qquad$
$-85-90 \%$ of those eligible

## Data collected

- Maternal and child questionnaires
- Prenatal nutrition
- Biomarkers
- FFQ in late pregnancy
- Other prenatal/childhood exposures/confounders $\qquad$
- DNA on 10,000 mothers and 10,000 children $\qquad$
- Respiratory and atopic phenotypes
- Early childhood wheezing phenotypes
- Asthma, wheezing and atopic disease at 6 years
- Skin test reactivity and total IgE at 7 years
- Lung function and BR (methacholine) at 8-9 years

Paracetamol use in late pregnancy and prevalence of wheezing at 30-42 months

| Frequency | n | $\%$ |
| :--- | ---: | ---: |
|  |  |  |
| Never | $608 / 5134$ | 11.8 |
| Some days | $561 / 3725$ | 15.1 |
| Most days/daily | $26 / 88$ | 29.5 |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Paracetamol use in late pregnancy and risk of wheezing at 30-42 months (Thorax 2002; 57: 958-63)

Frequency $\quad$ OR $(95 \% \mathrm{CI}) \quad$ Adj $\mathrm{OR}(95 \% \mathrm{CI})$
$\begin{array}{lll}\text { Never } & 1.00 & 1.00\end{array}$
Some days $\quad 1.34(1.18,1.52) \quad 1.12(0.98,1.28)$
Most days/daily $3.17(1.99,5.05) \quad 2.10(1.30,3.41)^{*}$
*P=0.003

## Paracetamol in pregnancy and childhood wheezing: Interpretation <br> MIRROR (LONDON, UK) <br> 30ht October 2002 <br> PREGNANT MUMS USING PAINKILLERS DOUBLE

 RISK OF ASTHMA IN BABIES DOC WARNS OF LINK- BUT
- Population Attributable Fraction $=\sim 1 \%$

## Causal inference in observational studies

- Bradford Hill "criteria"
- Size of effect
- Dose response
- Consistency
- Biological plausibility
- Temporality $\qquad$
$\qquad$
$\qquad$

## Strengthening causal inference

- Gene by environment interaction
- Modification of paracetamol effect by gene variants influencing toxicity: $\uparrow$ bio plausibility - nb human data lacking
- Glutathione-S-transferase
- GSTT1, GSTM1, GSTP1
- conjugates NAPQI with GSH $\qquad$
- Nrf2
- Knockout mice sensitive to paracetamol toxicity $\qquad$
- Disruption of Nrf2 leads to increased allergic inflammation in a mouse model of asthma

| Paracetamol use in early pregnancy and asthma risk stratified by maternal Nrf2 |  |  |  |
| :---: | :---: | :---: | :---: |
|  | Adj OR* | 95\% CI | P |
| $\mathrm{C}: \mathrm{C}(\mathrm{n}=3754)$ | 0.99 | 0.81 to 1.21 | 0.91 |
| $\mathrm{T}: \mathrm{C} / \mathrm{T}: \mathrm{T}(\mathrm{n}=1137)$ | 1.73 | 1.22 to 2.45 | 0.002 |
|  |  | Interaction | 0.02 |
| *Per category of exposure |  |  |  |
| No interaction with child Nrf2 genotype |  |  |  |

Risk of impaired lung function by maternal smoking and GSTM1

Overall: $-0.043^{*}(-0.069$ to -0.016$)$; $P$ trend 0.0017 $\qquad$
Child genotype $\qquad$
GSTM1 present: $\quad-0.017$ (-0.06 to 0.027)
GSTM1 null: $\quad-0.061(-0.10$ to -0.02$)$ $\qquad$
Maternal genotype
GSTM1 present: $\quad-0.019(-0.07$ to 0.033$)$
GSTM1 null:
-0.054 (-0.10 to -0.005)
*Age/height-adjusted deficit (95\% CI) in $\mathrm{FEF}_{25-75}$ (SDs) associated with smoking (per category increase)
$\qquad$
